

PROCEDURE FOR ENSURING THE OPERATION OF SIGNALLING
CHANNELS IN A V5 INTERFACE

B *send at* 1. Field of the Invention

B 5 The present invention relates to a procedure
as defined in the preamble of claim 1 for ensuring the
operation of protected signalling channels in a V5 in-
terface between a local exchange and an access node in
conjunction with a redefinition of the composition of
the interface.

10 B 2. Description of Related Art
Open interfaces (V5.1 and V5.2) between an
access node and a local exchange are defined in the
ETSI (European Telecommunications and Standards Insti-
tute) standards of the ETS 300 324 and ETS 300 347 se-
ries. V5 interfaces enable subscribers belonging to a
15 physically separate local network to be connected to a
telephone exchange using a standard interface. In the
present application, V5 interface expressly refers to
a dynamic concentrator interface (V5.2) as defined in
the ETS 300 347 standard series, consisting of one or
20 more (1 - 16) PCM (Pulse Code Modulation) cables. One
PCM cable comprises 32 channels, each of which with a
transfer rate of 64 kbit/s, i.e. 2048 kbit/s in all.
The V5.2 interface supports analogue telephones as us-
ed in the public telephone network, digital, such as
25 ISDN (Integrated Services Digital Network) basic and
system subscriber connections as well as other analo-
gue or digital terminal equipment based on semi-fixed
connections.

Certain time slots in the V5 interface, which
30 form a channel called C-channel, serve to transmit the
protocols used for controlling the interface itself
and the calls transmitted over the interface. A C-
channel or a 64 kbit/s time slot reserved for this
purpose serves to transmit information that may belong
35 e.g. to the Control protocol, Link control protocol,
Protection protocol or BCC protocol of the V5 interfa-
ce, or which may consist of PSTN signalling or ISDN

2

data. Further, according to the standards mentioned above, a C-channel can be reserved for time slots 16, 15 and/or 31 in the PCM line or V5 interface link. Especially in a V5.2 interface, the system automatically
5 creates C-channels for the critical protocols (Control, Link control, BCC and Protection), whereas the operator can place the PSTN signalling as desired, either in the same channel with the critical protocols or in another C-channel. In addition, the operator may
10 allocate a maximum of three signalling channels as so-called backup channels. These channels are resorted to in the case of a failure of the link to which the channels were originally allocated. In a V5.2 interface having more than one 2-Mbit/s link, a link whose
15 physical C-channel in time slot 16 transmits the Control, Link control, BCC and Protection protocols is defined as the primary link. Further, a link whose physical C-channel in time slot 16 only transmits the Protection protocol is a secondary link.

20 The above-mentioned standards define two different ways of changing the data for a V5 interface already activated. Changing the data means e.g. that a signalling channel is transferred to another time slot or that additional signalling channels are introduced.
25 Such changes can be effected using the so-called reprovision function defined in the standard, in which case the altered data are given a new "designation" (provision variant) at both ends, i.e. in the local exchange and in the access node. The provision variant
30 is a parameter which is checked in conjunction with the start-up of the V5 interface. This verification serves to ensure that both the local exchange and the access node observe the same composition in the V5 interface. Composition means in the first place the lo-
35 cations and order of the signalling channels. When the parameter in question is assigned a new value, this means that e.g. the signalling channels have a new lo-

5 cation. When the changes are activated at both ends,
i.e. when the interface is started up, the hardware
first ensures via signalling that the new value of the
"provision variant" is known at both ends, whereupon
10 the changes of composition or configuration are made
independently according to the parameter in question.
However, it is also possible to make changes in the V5
interface without using the reprovision function. In
this case, the changes are made independently at both
15 ends without altering the value of the provision vari-
ant parameter. When the changes are activated, the de-
fined changes are made automatically at both ends and
the interface is started up.

20 The locations of the signalling channels in
an active interface may change in consequence of a
protection switch-over of a signalling channel. This
creates a situation where the interface configuration
is no longer consistent with the configuration origi-
nally defined by the operator. The problem is that the
25 above-mentioned standards do not define whether the
possible protection switch-over cases should be taken
into account or not when a new configuration or compo-
sition is introduced. Further, when the composition of
the interface is being defined, it must also be taken
30 into account that one of the links may have been dama-
ged and that consequently the signalling channels
transmitted via that link are switched over to another
link. Figures 1a and 1b present an example of such a
situation. Fig. 1a illustrates normal operation bet-
35 ween a local exchange LE and an access node AN. In
this V5 interface, the signalling channel, which may
be e.g. the BCC protocol, has been allocated to the
topmost link in the V5 interface. Further, a backup
channel has been allocated to the bottommost link in
the interface. Fig. 1b illustrates an example situati-
on where the backup channel and signalling channel are

4

swapped, i.e. the signalling channel is switched over to the backup channel when the link is damaged.

B

~~SUMMARY OF THE INVENTION~~

The object of the present invention is to eliminate the problems described above. A specific object of the present invention is to present a new procedure that makes it possible to flexibly ensure the activation of the signalling channels in a V5 interface when a new composition is defined for the V5 interface without the reprovision function.

10 In the procedure of the invention, in a V5 interface between a local exchange and an access node, said interface comprising at least two links, to ensure the operation of the signalling channels in conjunction with a redefinition of the interface composition, in which redefinition changes are made in the V5
15 interface data, such as the placement of signalling channels on the links, according to the invention, the operation of protected channels is ensured in conjunction with restarting by activating the protected
20 channels on the channels defined for them in the new composition and/or on the channels to which they were transferred in conjunction with the protection switch-over. The redefinition of the V5 interface composition is preferably carried out independently both in the
25 local exchange and in the access node without changing the value of the interface composition parameter.

In an embodiment of the invention, the channels transferred to a backup channel in conjunction with protection switch-over are left at the locations
30 to which they were transferred in conjunction with the switch-over, regardless of the redefined composition of the V5 interface.

In an embodiment of the invention, changes in conjunction with a redefinition of the composition of
35 a V5 interface are made in the original composition regardless of protection switch-over operations carried out in the V5 interface.

⁵
BRIEF DESCRIPTION OF THE DRAWINGS

b In the following, the invention will be described by the aid of a preferred embodiment by referring to the attached drawings, in which

Fig. 1a represents a V5 interface according to the invention;

Fig. 1b represents a functional state of the V5 interface in Fig. 1a;

Fig. ^{2a}~~1b~~ represents a functional state according to the present invention; and

Fig. 2b represents another functional state according to the present invention.

b DETAILED DESCRIPTION OF THE INVENTION

Figures 1a and 1b present a V5 interface according to the invention between a local exchange LE and an access node AN. In Fig. 1a, a signalling channel has been configured to use the topmost link in the V5 interface. Further, a backup channel to which one of the signalling channels can be switched over has been configured to be carried by the bottom link. In Fig. 1b, a switch-over of the signalling channel to the backup channel is carried out due to malfunction of the top link, in other words, the signalling channel originally allocated to the top link is transferred to the bottom link in place of the backup channel.

Fig. 2 illustrates a solution according to the invention for ensuring the activation of the signalling channels when a new V5 interface composition is defined without using the reprovision function. In the solution presented in Fig. 2, when a backup configuration is introduced, protection switch-overs of signalling channels carried out previously in the interface are taken into account. In practice, this means that the signalling channels already switched over as illustrated by Fig. 2a are left at the locations to which they have been transferred in consequence of protection switch-over, in this case on the lowest link, and not at the locations where they were placed in the original configuration. Further, in Fig. 2a a

redefinition has been performed in which it has been decided that the original backup channel, which has been on the lowest link as shown in Fig. 1a, shall be removed. The system removes it based on the situation after the switch-over, so in this case the backup channel is removed from the physical location that in the operator's original composition contained a signalling channel (from the top link). Fig. 2b illustrates another solution according to the invention for ensuring the activation of signalling channels. In the arrangement presented in Fig. 2b, the changes are made in the composition originally created in the system by the operator, without taking into account any protection switch-overs carried out before. Thus, in a situation as illustrated by Fig. 2b, the system removes the signalling channel from the physical location where the operator had originally placed it, in this case from the lowest link.

The invention is not restricted to the examples of its embodiments described above, but many variations are possible within the scope of the inventive idea defined by the claims.
